Drinking alcohol is a risk factor contributing to seven types of cancer. The more alcohol you drink, the greater the risk of developing cancer. This factsheet explains how high these risks are, which types of cancer are more likely, how alcohol causes cancer, and gives you guidelines on how to keep your risk low.

Alcohol is a group 1 carcinogen, which means that there is enough evidence to show that alcohol causes cancer. Other group 1 carcinogens include UV radiation and tobacco smoke. Alcohol causes 3.3% of cancer cases in the UK, which is around 11,900 cases per year. To put this in context, tobacco smoking causes 15% of cancer cases in the UK.

The evidence shows that any amount of alcohol can increase the risk of cancer, but drinking 14 units a week or less will keep the risk low.

Alcohol causes around 11,900 cases of cancer per year in the UK.

There is strong evidence that drinking up to two drinks per day can decrease the risk of kidney cancer (1). But remember, if you are drinking to decrease your risk of kidney cancer, you will still be increasing your risk of the other cancers listed above, as well as other alcohol-related conditions such as diabetes, hypertension and liver disease. Alcohol may also be linked to other cancers such as lung, pancreatic and skin cancer, but more research is needed before we can be certain.

How does alcohol cause cancer?

The exact way that alcohol causes cancer is not fully understood. The current best evidence shows that acetaldehyde (a chemical produced when the body breaks down alcohol) is toxic and damages the DNA in our cells, which causes cancer. Other explanations include:

- Alcohol directly damages cells it comes into contact with, for example in the mouth, throat and stomach, which makes it easier for other cancer-causing compounds, such as ones from tobacco or processed meats, to get into the cells and cause DNA damage.
- Drinking alcohol can lead to liver cirrhosis. This is when the liver is damaged over time and forms scarring. Having cirrhosis is known to increase the risk of liver cancer.
- If you drink high levels of alcohol you may not be getting enough nutrients in your diet, which has the knock-on effect of making you more susceptible to cancer.

How can I reduce my risk?

The evidence shows that any amount of alcohol can increase the risk of cancer, but drinking within the guidelines will keep the risk low. The UK guidelines recommend you drink no more than 14 units of alcohol per week, spread evenly over three or more days and with a few days off. Fourteen units is roughly equivalent to six pints of beer or one and a half bottles of wine.

If you currently drink a lot, reducing the amount you drink now will still decrease your risk of cancer compared to if you keep drinking at high levels.

Does it matter what I drink?

Any drink containing alcohol increases the risk of cancer. This includes beer, wine, spirits, cider and fermented milks. This is because it is the pure alcohol itself, ethanol, which causes cancer, not the other ingredients in these drinks. Stronger drinks, such as spirits, contain more pure alcohol than weaker drinks, such as beer, because they are more concentrated. So, if one person drank the same amount of spirits as another person drank beer, the person drinking spirits would be at a greater risk of developing cancer.
